<p><b>14. ABSTRACT</b></p> <p>The protected status of false killer whale (<i>Pseudorca crassidens</i>) populations in Hawaiian waters, combined with limited data on population sizes and trends in their abundance, makes it critical to develop monitoring methods and to mitigate negative interactions between false killer whale populations and anthropogenic activities. Acoustic methods are well-suited for studying and monitoring this species, due to its soniferous (i.e., sound-producing) nature. Continued development of methods for detection and classification of marine mammal sounds requires extensive datasets for training classifiers and ground-truthing detection algorithms. The cabled, seafloor-mounted hydrophones at the Pacific Missile Range Facility (PMRF) off of the northwest side of the island of Kauai produce vast amounts of data that could significantly augment training and validation datasets if species identity of sounds in the recordings could be confirmed. Some of the recordings made at PMRF have been made coincident with the presence of marine mammals equipped with satellite tags, providing some evidence for species identity; however, these recordings do not have associated visual observations, and so it is not possible to determine whether other species are in the area based on tag data alone. A second source of information on species identity could provide further supportive evidence for species identity in the recordings and could indicate whether or not other species are present in the area. In this project, we examine the potential of this approach by using Real-time Odontocete Call Classification Algorithm (ROCCA) to classify whistles recorded in the presence of satellite-tagged false killer whales at PMRF.</p> <p>Recordings were collected from five seafloor-mounted hydrophones within the PMRF. Recordings were made on different hydrophones as false killer whales equipped with satellite tags moved throughout the range. Recordings from</p>		

the hydrophones closest to the tagged animals during tag updates (animal location readings obtained from the tags) were provided to Bio-Waves, Inc. by Space and Naval Warfare Systems Command (SPAWAR) Systems Center, Pacific for eight tag update periods. Tag updates included the depth and location of the tagged animal so it was possible to determine the horizontal distance between the tagged animal, so it was possible to determine the horizontal distance between the tagged animal and the PMRF hydrophone. A total of 2 hours and 10 minutes of recordings were provided by SPAWAR for this analysis. Fifty logged whistles were randomly chosen for classification analysis from each 10-min .wav file. Whistle contours were extracted, measured and classified using the ROCCA module in PAMGuard (Gillespie et al. 2008, Oswald et al. 2013).

The random forest classifier used to analyze the PMRF data was a two-stage model that was trained using whistles recorded in the eastern tropical Pacific Ocean. All encounters in the dataset were classified as false killer whales. Because the recordings were made when tagged false killer whales were less than 2 nautical miles (NM) from the PMRF hydrophones, it was assumed that the vocalizations recorded were produced by false killer whales. However, there were no visual observations associated with the recordings, so it is possible that other species were also present within acoustic range of the hydrophones. The fact that all encounters were classified as false killer whales (based on the recorded whistles) provides a second source of evidence to support the hypothesis that the recorded sounds were produced by false killer whales.

Classification results that match the species of tagged animal in the area provide a higher level of confidence for species identification of the recordings. As a result, these recordings could be used to train and test other classifiers. In addition, the annotated dataset provides much-needed data for ground-truthing automated detectors. Annotated datasets are time- and cost-intensive to produce, and so these data are a valuable addition to existing annotated datasets.

# 1. Introduction

Three populations of false killer whales (*Pseudorca crassidens*) are identified in Hawaiian waters based on genetic, photo-identification, and movement data (Chivers et al. 2010; Baird et al. 2010, 2013; Martien et al. 2014). One of these populations, the Main Hawaiian Islands Insular stock, is listed as endangered under the Endangered Species Act and automatically considered to be a 'strategic stock' under the Marine Mammal Protection Act. The Hawaii Pelagic stock is not listed as threatened or endangered under the Endangered Species Act, but is considered to be a 'strategic stock' under the Marine Mammal Protection Act. The third population, the Northwestern Hawaiian Islands stock, is not listed as threatened or endangered under the Endangered Species Act; however, little is known about population size or trends in abundance for this stock (Carretta et al. 2015). False killer whales have received increased attention in recent years due to interactions with Hawaii-based longline fisheries leading to excessive bycatch (Forney and Kobayashi 2007, Baird et al. 2010). The status of these populations/stocks, combined with limited data on population sizes and trends in abundance, makes it critical to develop monitoring methods and to mitigate negative interactions between false killer whale populations and anthropogenic activities.

False killer whales are soniferous (i.e., sound producing) animals that produce a variety of whistle, click, and pulsed sounds (Murray et al. 1998). Acoustic methods are therefore well suited for studying and monitoring this species. Autonomous acoustic recorders are being used increasingly to study many marine mammal species, including false killer whales (Mellinger et al. 2007). Two challenges inherent to the use of autonomous recorders are: 1) efficient analysis of the large volumes of data that they produce, and 2) the ability to identify recorded sounds to species. The development of algorithms for automated or semi-automated detection and classification of marine mammal sounds is an active field of research, and several software platforms are now available for accomplishing these tasks (Mellinger et al. 2011, Roch et al. 2011, Gillespie et al. 2013). One such platform is PAMGuard, which contains a module called Real-time Odontocete Call Classification Algorithm (ROCCA) for dolphin whistle classification (Gillespie et al. 2008, Oswald et al. 2013b). ROCCA has been used to analyze acoustic recordings made around the Hawaiian Islands as well as the Mariana Islands and the northwest Atlantic Ocean (Norris et al. 2012, Oswald 2013, Oswald et al. 2013a).

Development of methods for detection and classification of marine mammal sounds requires extensive datasets for training classifiers and ground truthing detection algorithms. Acoustic recordings with associated visual observations of species identity are costly and time-consuming to collect and therefore large datasets of single-species recordings are rare. The ability to use recordings made with autonomous recorders to train and ground truth algorithms would be a valuable asset. The cabled, seafloor-mounted hydrophones at the Pacific Missile Range Facility (PMRF) off of the northwest side of the island of Kauai produce vast amounts of data that could significantly augment training and validation datasets if species identity of sounds in the recordings could be confirmed. Some of the recordings made at PMRF have been made coincident with the presence of marine mammals equipped with satellite tags, providing some evidence for species identity; however, these recordings do not have associated visual observations, and so it is not possible to determine whether other species are in the area based

on tag data alone. A second source of information on species identity could provide further supportive evidence for species identity in the recordings and could indicate whether or not other species are present in the area. In this project, we examine the potential of this approach by using ROCCA to classify whistles recorded in the presence of satellite-tagged false killer whales at PMRF.

## 2. Methods

### 2.1 Recordings

Recordings were collected from five seafloor-mounted hydrophones within the PMRF. Recordings were made on different hydrophones as false killer whales equipped with satellite tags moved throughout the range. Recordings from the hydrophones closest to the tagged animals during tag updates (animal location readings obtained from the tags) were provided to Bio-Waves, Inc. by SPAWAR (Space and Naval Warfare Systems Command) Systems Center, Pacific for eight tag update periods. Tag updates included the depth and location of the tagged animal, so it was possible to determine the horizontal distance between the tagged animal and the PMRF hydrophone. Each Waveform Audio File Format (.wav) file provided by SPAWAR was 10 minutes in duration and was sampled at 96 kilohertz with 16-bit resolution. **Table 1** gives information about these recordings, including hydrophone depths and approximate horizontal distances between the hydrophones and the tagged animals. A total of 2 hours and 10 minutes of recordings were provided by SPAWAR for this analysis.

**Table 1. Filenames, hydrophone numbers and depths and horizontal distances between tagged false killer whales and hydrophones for .wav files provided to Bio-Waves, Inc. by SPAWAR Systems Center, Pacific.**

## 2.2 Annotation of Echolocation Clicks, Buzzes and Whistles

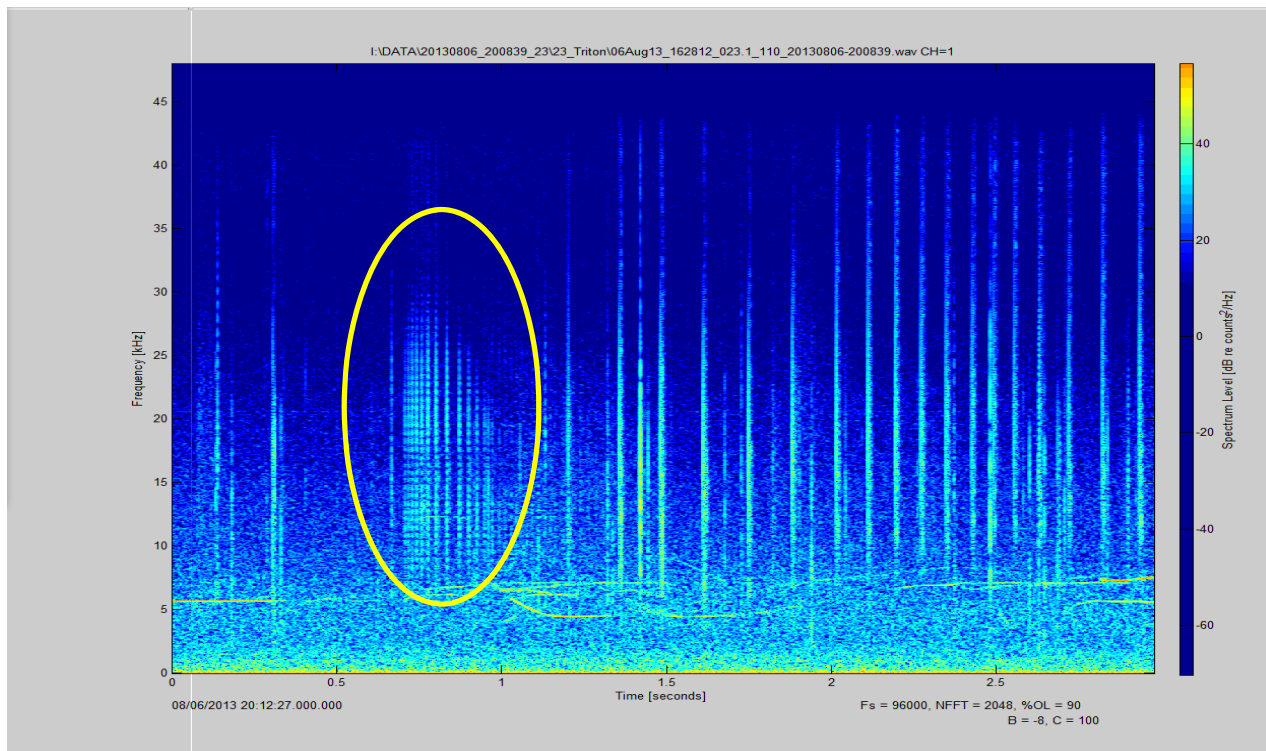

A bioacoustic analyst annotated each 10-minute .wav file using the MATLAB-based software Triton (Wiggins 2007). The start time of each echolocation click (**Figure 1**) and buzz (any train of rapid clicks with an inter-click interval no greater than 40 milliseconds; **Figure 2**) were logged by examining both the spectrogram and the time series view in Triton software. No clicks that were less than 0.3 amplitude counts<sup>1</sup> within the time series were logged, and multipath signals (i.e., echoes or bottom/surface bounces) were not logged (**Figure 1**). When all echolocation clicks and buzzes had been noted, the analyst made a second pass through the file to log the start and end time of every whistle. Only whistles with a signal-to-noise ratio of 8.1 or higher were logged (**Figure 3**). Whistles contours without a clear start or end were not logged, and harmonics were not logged.

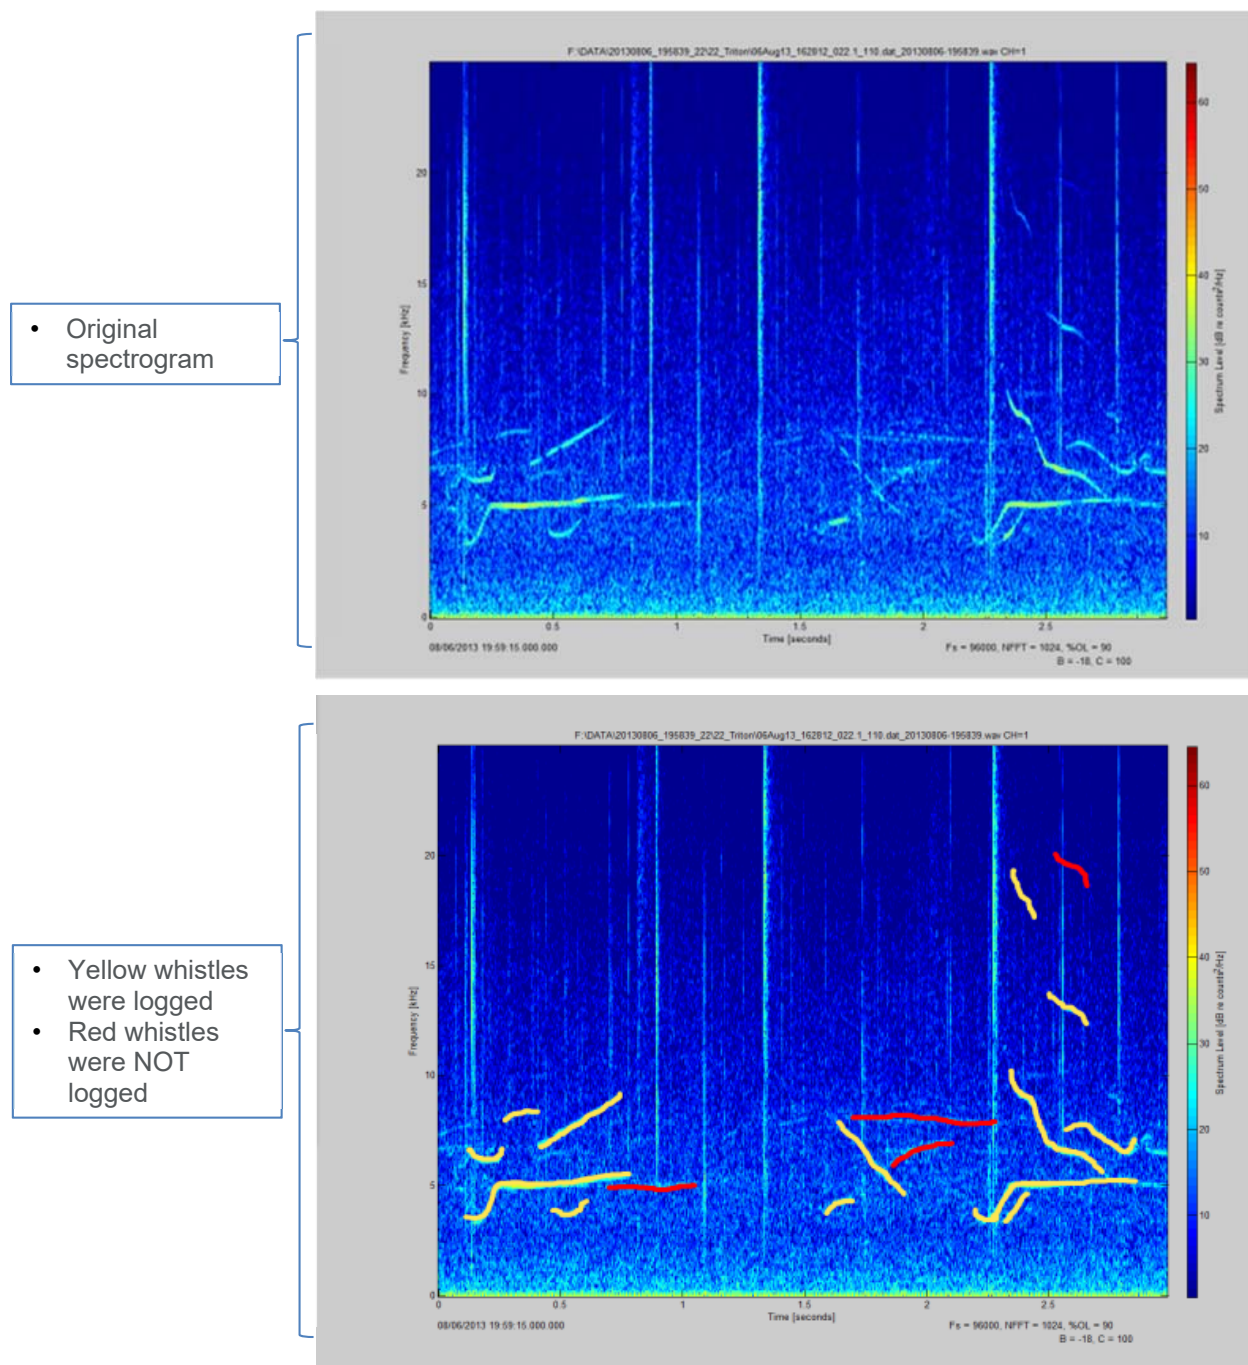

**Figure 1. Spectrogram and waveform view of false killer whale echolocation clicks in Triton software.** Yellow circles are echolocation clicks that were logged. Clicks that are not circled are faint and/or multipath signals that were not logged.

<sup>1</sup> Counts are typically the integer output from an analog-to-digital converter. For example, a 16-bit analog-to-digital converter may have a range of 0-5 volts (V) which is converted to counts  $\pm 2^{15}$  ( $\pm 32768$ ), so one count is  $5V/2^{16} = 76.3$  microvolts. Volts can then be converted into pressure (typically micropascals and frequency dependent) if the hydrophone and signal conditioning electronics transfer function is known.

## 2.3 Classification analysis

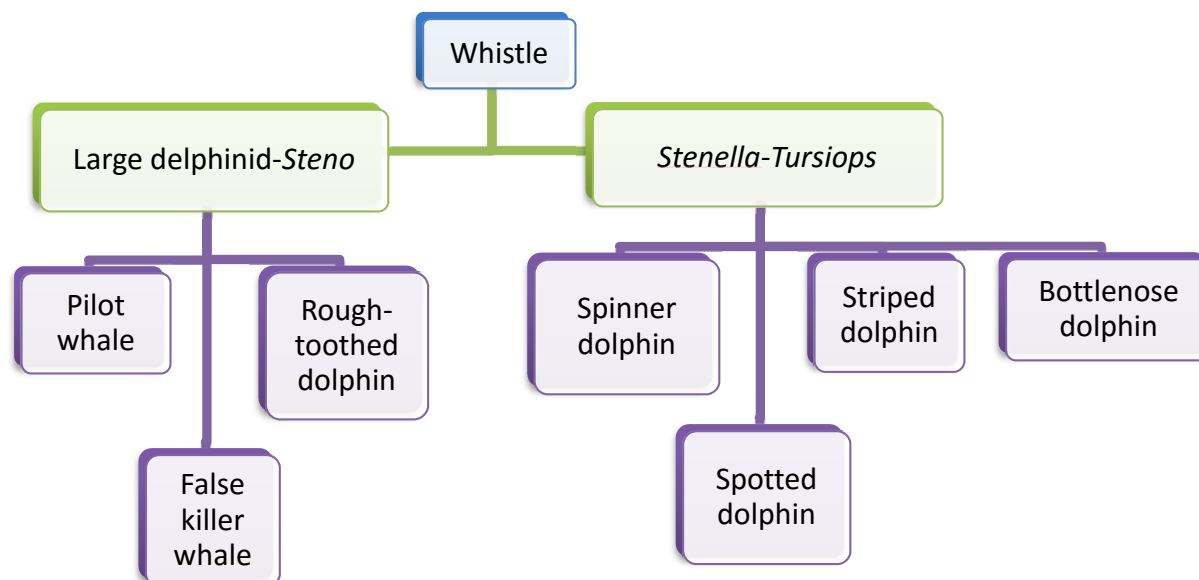

Fifty logged whistles were randomly chosen for classification analysis from each 10-minute .wav file. Whistle contours were extracted, measured and classified using the ROCCA module in PAMGuard (Gillespie et al. 2008, Oswald et al. 2013). Time-frequency contours were extracted from whistles by using a computer touch-pad to manually trace contours on ROCCA's spectrographic display. ROCCA automatically extracted and saved the time-frequency values of

the traced contours and then measured 50 variables from each contour. These variables included duration, frequencies (e.g., minimum, maximum, beginning, ending, and at various points along the whistle), slopes, and variables describing whistle shape (e.g., number of inflection points and steps; see Barkley et al. 2011 for a complete list and description of variables measured).

When whistle contours had been extracted and measured, ROCCA's random-forest classifier was used to automatically identify 'acoustic encounters' to species. Each 10-minute .wav file was considered an independent acoustic encounter, even though multiple recordings on the same day were associated with one tagged animal. This approach was taken because species composition in the study area may change both spatially and temporally. For example, if other species move into the area and are recorded by the PMRF hydrophone, there is a greater chance that they will be identified by ROCCA if each 10-minute recording is considered independently.

A random forest is a predictive model containing a collection of decision trees grown using binary partitioning of the data. Each binary partition of the data is based on the value of one feature (in this case, a whistle feature; Breiman 2001). Randomness is introduced into the tree-growing process by examining a random subsample of all of the features at each node. The feature that produces the most homogeneous split is chosen at each partition. When whistle features are analyzed using a random forest, each of the trees in the forest produces a species classification. Classifications are then tallied over all trees and the whistle is classified as the species that received the highest proportion of classifications. In addition to classifying individual whistles, overall acoustic encounters were classified based on the number of tree classifications for each species, summed over all of the whistles that were analyzed for that encounter.

The random forest classifier used to analyze the PMRF data was a two-stage model that was trained using whistles recorded in the eastern tropical Pacific Ocean. All recordings included in the training dataset were recorded from single-species schools that had visual confirmation of species identity and were at least 3 nautical miles (NM) from any other visual or acoustic detection of whistling species. Seven species were included in the classifier: short-finned pilot whale (*Globicephala macrorhynchus*), false killer whale, pantropical spotted dolphin (*Stenella attenuata*), bottlenose dolphin (*Tursiops truncatus*), rough-toothed dolphin (*Steno bredanensis*), striped dolphin (*Stenella coeruleoalba*), and spinner dolphin (*Stenella longirostris*). The first stage of the classifier classified whistles to one of two categories: 'large delphinid-*Steno*' (including false killer whales, pilot whales and rough-toothed dolphins) and '*Stenella-Tursiops*' (including spinner, spotted, striped and bottlenose dolphins). In stage two of the classifier, whistles within each category were then classified to species (**Figure 4**). Both stages consisted of 800 trees. In each stage, the training dataset was subsampled so that there were an equal number of whistles for each species or species-group. This prevented an overrepresentation of any single class, which could skew the results. The performance of the classifier was tested using 10-fold cross validation, and classification success was evaluated by comparing the percentage of encounters correctly classified for each species to the correct classification score that would be expected by chance alone (e.g., 14 percent for 7 species; **Table 1**).

**Figure 4. Schematic diagram of the two-stage random forest classifier.** In stage one, whistles are classified to one of two broad categories ('large delphinid-Steno' or '*Stenella-Tursiops*'). In stage two, whistles within each category are classified to individual species or species-group.

## 3. Results

### 3.1 Annotations

Echolocation clicks, buzzes, whistles and pulsed calls were annotated from all 13 .wav files. One annotation log was compiled for each .wav file. These logs included start times for each echolocation click and start and end times for each whistle, buzz and pulsed call in the recordings. Annotation logs are included as supplemental material to this report (see **Appendix A**).

### 3.2 Classification Analysis

Overall, 90 percent of encounters were correctly classified in the eastern tropical Pacific training dataset. All correct classification scores were significantly greater than expected by chance alone (**Table 2**, Fisher's exact test,  $\alpha = 0.05$ ).

**Table 2. Confusion matrix for the two-stage random forest classifier used to classify whistles recorded with the PMRF hydrophones.** The percentage of encounters correctly classified for each species is in bold. The number of encounters and total number of whistles in the testing and training dataset are given for each species.

Actual species	Pilot whale	False killer whale	Percent classified as					n encounters	n whistles
			Spotted dolphin	Rough-toothed dolphin	Striped dolphin	Spinner dolphin	Bottlenose dolphin		
<b>Pilot whale</b>	<b>83</b>	0	0	0	17	0	0	12	109
<b>False killer whale</b>	0	<b>100</b>	0	0	0	0	0	9	309
<b>Spotted dolphin</b>	0	0	<b>94</b>	0	6	0	0	17	204
<b>Rough-toothed dolphin</b>	0	0	0	<b>83</b>	8	8	0	12	145
<b>Striped dolphin</b>	0	3	3	3	<b>91</b>	0	0	36	452
<b>Spinner dolphin</b>	0	0	0	7	<b>0</b>	<b>93</b>	0	14	170
<b>Bottlenose dolphin</b>	0	0	0	13	0	0	<b>88</b>	8	155

All encounters were identified as false killer whales by the random forest classifier. Not every whistle in every encounter was classified as false killer whale, but false killer whales received the most tree votes when summed over all of the classified whistles in each encounter (**Table 3**). In every encounter, rough-toothed dolphins received the second highest number of tree votes.

**Table 3. Number of whistles classified as each species in each .wav file and the number of tree votes summed over all of the whistles classified in each encounter.**

## 4. Discussion

All encounters in the dataset were classified as false killer whales. Because the recordings were made when tagged false killer whales were less than two NM from the PMRF hydrophones, it was assumed that the vocalizations recorded were produced by false killer whales. However, there were no visual observations associated with the recordings, so it is possible that other species were also present within acoustic range of the hydrophones. The fact that all encounters were classified as false killer whales (based on the recorded whistles) provides a second source of evidence to support the hypothesis that the recorded sounds were produced by false killer whales.

It is still possible that other species were in the area. Only a subsample ( $n=50$ ) of the hundreds of whistles in the recordings was analyzed, and if other species were in the area, it is possible that their whistles were not well represented in the subsample chosen for analysis. In addition, the ROCCA classifier identifies each encounter as only one species, even if multiple species are present. For many of the analyzed encounters, 20 percent or more of whistles were identified as rough-toothed dolphins. This may indicate that rough-toothed dolphins were also present in the area. There were two tagged rough-toothed dolphins present on the range during the time period in question; one on 6 August and one on 11 August (Baird et al. 2014). The tag data show that during the time periods analyzed, these animals were at least five NM away from the hydrophones included in the analysis. Because of this distance, it is unlikely that any of the whistles included in the analysis were produced by the tagged rough-toothed dolphins. However, this does not exclude the possibility that there were other rough-toothed dolphins in acoustic range of the hydrophones. Whistles classified as rough-toothed dolphins may have been produced by rough-toothed dolphins, but they may also be misclassifications due to the fact that false killer whales and rough-toothed dolphins both have relatively low frequency whistles compared to most of the other species included in the classifier (Oswald et al. 2007). Bio-Waves, Inc. is currently working on a project funded by the Office of Naval Research and the Living Marine Resources Program to incorporate information from echolocation clicks and information describing vocal behavior into the classifier. The inclusion of additional information in the classifier should reduce confusion among species that have similar whistle characteristics. Future work should also include developing methods for identifying mixed-species schools.

Nevertheless, classification results that match the species of tagged animal in the area provide a higher level of confidence for species identification of the recordings. As a result, these recordings could be used to train and test other classifiers. In addition, the annotated dataset provides much-needed data for ground truthing automated detectors. Annotated datasets are time- and cost-intensive to produce, and so these data are a valuable addition to existing annotated datasets.

## 5. Acknowledgements

We would like to thank Steve Martin at SPAWAR for providing the acoustic data for this work and Robin Baird (Cascadia Research Collective) for providing the tag data. We also thank Commander, U.S. Pacific Fleet for funding that made this work possible.
